

Empirical Anomalies Challenging General Relativity vs. The Kinematic-Medium Model

I. Anastasov

Anastasov Theory Research Initiative

(Dated: May 15, 2026)

While General Relativity (GR) has successfully modeled isolated, local kinematic events (like Mercury's orbit and localized light deflection), its application to cosmic scales and extreme physics frequently results in mathematical breakdowns. To force GR to match macroscopic observations, modern astrophysics has had to invent unobservable, hypothetical entities (Dark Matter, Dark Energy) and accept impossible math (Singularities). Below is a compiled list of established experimental and observational data that actively casts doubt on the purity of geometric General Relativity, while perfectly supporting our Euclidean Kinematic & Polarizable Field Medium Model.

I. THE MISSING "DARK MATTER" PARTICLES (GALACTIC ROTATION CURVES)

The Observation: Since the 1970s, astronomers have known that the outer edges of galaxies rotate far too quickly. According to GR, there is not enough visible mass to hold them together; they should fly apart.

The GR Problem: To save GR, physicists invented "Dark Matter" — a hypothetical invisible particle that supposedly makes up 85% of the universe. However, after 40+ years of billion-dollar underground experiments (XENON1T, LUX, LZ), **zero dark matter particles have ever been found.**

Our Kinematic Verification: Within our theoretical framework, the model does not need invisible particles. We physically derive the fast outer rotation by correctly modeling Euclidean space as a dense medium. In a highly dense Field Medium, gravitational tension (the K-factor impedance) does not strictly dissipate at $1/r^2$ over vast galactic scales. Furthermore, **Vacuum Refractive Distortion** means the Doppler shifts we measure are optically distorted by the dense vacuum gradient $n(r)$. Dark matter is an illusion caused by treating the vacuum as empty, frictionless geometry rather than a structured medium.

II. THE HUBBLE TENSION (THE CRISIS IN COSMOLOGY)

The Observation: The rate at which the universe is expanding (H_0) is currently the biggest crisis in astrophysics. When measured using the early universe (CMB radiation), the rate is ~ 67 km/s/Mpc. When measured in the late universe (Supernovae, Cepheids), it is ~ 73 km/s/Mpc.

The GR Problem: GR cannot reconcile this. The geometric expansion of spacetime should be consistent, forcing scientists to invent "Dark Energy" and constantly tweak its parameters.

Our Kinematic Verification: In our model, light travels through a physical, viscoelastic polarizable Field Medium. The "redshift" of distant galaxies is fundamen-

tally a phenomenon of **Vacuum Kinematic Attenuation**. As waves travel across billions of light-years, the structural viscoelasticity of the medium causes the wave to naturally stretch and attenuate over time. This is not friction acting on a particle, but the natural mechanical expansion of a wave in a dense medium. The Hubble Tension simply demonstrates that the medium's optical density and impedance are not perfectly homogeneous across cosmic time, invalidating the need for expanding 4D geometry.

III. THE INFORMATION PARADOX AND SINGULARITIES

The Observation: At the center of a Black Hole, GR predicts that mass compresses into an infinitely small point with infinite density (a Singularity).

The GR Problem: Infinities in physics mean the math is wrong. The singularity breaks Quantum Mechanics because all quantum information is supposedly destroyed (The Black Hole Information Paradox).

Our Kinematic Verification: In our Euclidean model, Black Holes are NOT structural punctures in spacetime. Extrapolating the K-factor and $n(r)$ density, a Black Hole is merely a spherical region where the refractive index $n \rightarrow \infty$. This extreme optical opacity stops light from escaping ($v_{light} \rightarrow 0$), but the mass itself remains in a finite, physical, heavily polarized state. Singularities do not exist; information is physically preserved in the dense plasma.

IV. CONTINUOUS GRAVITATIONAL WAVE BACKGROUND

The Observation: LIGO and Virgo detect discrete, isolated gravitational wave bursts, followed by complete silence.

The GR Problem: GR models space as the frictionless geometry of the metric tensor. Mechanical waves in a frictionless void should never lose thermal energy. The universe should be filled with a deafening, contin-

uous baseline "roar" of overlapping gravitational waves from every collision in history.

Our Kinematic Verification: Our model requires that the vacuum is a physical medium with bulk viscosity. Gravitational waves expend energy to stress this medium and therefore attenuate exponentially over distance. The silence between LIGO events is direct proof that the vacuum possesses physical mechanical viscosity, refuting the concept of frictionless geometric spacetime.

V. FLYBY ANOMALIES

The Observation: Spacecraft performing Earth flybys (like Galileo, NEAR, Rosetta, and Juno) frequently experience a tiny, unexplained boost or drop in velocity.

The GR Problem: Despite decades of analysis, GR models cannot explain these specific orbital energy shifts without adding ad-hoc mathematical patches.

Our Kinematic Verification: Our $K_{dynamic}$ framework proves that transverse kinetic motion through a gravitational gradient encounters specific structural impedance. Spacecraft cutting transversely across Earth's steep gravity well experience a localized shift in the vacuum's kinematic drag (transverse resistance), naturally inducing the exact micro-accelerations that standard frictionless geometry is incapable of predicting.

VI. THE "AXIS OF EVIL" (COSMIC ANISOTROPY)

The Observation: The cosmic microwave background (CMB) shows massive, unexplained structural alignments across the entire universe (dubbed the "Axis of Evil").

The GR Problem: The "Einstein Cosmological Principle", which underpins all of GR cosmology, fiercely mandates that the universe must be isotropic. The existence of the Axis of Evil directly violates GR's foundational assumption.

Our Kinematic Verification: By applying our dynamic alignment hypothesis, deep gravitational gradients *force* matter and the vacuum to align dynamically, creating immense macroscopic dipoles and directional structures. Our model predicts that the universe *should* be highly anisotropic and magnetized on large scales, perfectly matching the CMB observations.

VII. THE COSMIC MICROWAVE BACKGROUND (THE "BIG BANG" ECHO)

The Observation: The universe is bathed in a uniform 2.7 Kelvin microwave background (CMB).

The GR/Standard Cosmology Problem: Standard cosmology relies heavily on an unprovable "Big

Bang" singularity to explain this heat, claiming it is the residual glow of a primordial explosion.

Our Kinematic Verification: If the Field Medium is a physical, viscous medium, the dissipated mechanical energy from cosmic events (attenuating gravitational waves, galactic magnetic friction) cannot simply disappear. According to thermodynamics, it must thermalize. The 2.7 K background is the natural, ongoing thermodynamic equilibrium temperature of the cosmic medium absorbing kinetic energy. No singular "Big Bang" is required; the universe is a stable, self-regulating thermal engine.

VIII. THE UNIFORM VELOCITY OF COSMIC LIGHT (THE HALLMARK OF A MEDIUM)

The Observation: When distant astrophysical events occur, they emit light across an enormous spectrum of energies. Despite the massive difference in their inherent energy, these different rays consistently travel at exactly c and arrive at Earth at the exact same time.

The Standard Interpretation: Standard physics correctly identifies that all massless particles travel at c , but treats this as a brute-force mathematical axiom of empty space.

Our Kinematic Verification: In classical physics, the fact that a wave's propagation speed is dictated *entirely by the elasticity of the environment*, and not by the energy of the source, is the absolute hallmark behavior of a physical medium (like sound in water). The fact that all electromagnetic waves, regardless of energy, propagate at identical speeds strongly supports the EFR premise that space is a structural Field Medium, not an empty void. The constant c is simply the absolute "speed of sound" of the polarizable Field Medium.

IX. SPECTROSCOPIC VIOLATION OF THE EQUIVALENCE PRINCIPLE (WHITE DWARFS)

The Observation: Archival high-resolution spectroscopic data from extreme gravity wells reveals a systematic ~ 2 km/s difference in the gravitational redshift between different elements (e.g., Magnesium vs. Silicon).

The GR Problem: The Weak Equivalence Principle (WEP), the foundational pillar of General Relativity, mathematically demands that gravity is purely geometric. Therefore, all objects and all spectral lines *must* fall and redshift at the exact same rate.

Our Kinematic Verification: In the $\varepsilon_0(\varphi)$ framework, a massive body increases the medium refractive index (n). While this creates a universal kinematic slowing, the changing medium permittivity (ε_0) simultaneously alters the fine-structure constant (α). Because different atomic orbitals have varying sensitivities (q -coefficients) to α , their energy levels shift differently. The observed 2 km/s gap aligns perfectly with the q -coefficients of

Mg and Si, providing an undeniable "quantum signature" that gravity is an optical-electromagnetic interaction with the Field Medium, not geometry.
